

## GS301 Programmable Linear Hall-Effect IC

- GaAs + Si Hybrid Programmable Linear Hall-Effect IC
- Single power supply : VDD 3V ~ 5.5V
- Analog Fixed or Ratiometric Output
- Wide ambient Temperature Range : Ta -40°C ~ 125°C
- Quick response for magnetic field with wide bandwidth
- Programmable via One Wire Interface at Vout Pin

### Output Characteristics

|   | Pinning |
|---|---------|
| 1 | VDD     |
| 2 | GND     |
| 3 | VOUT    |
| 4 | VBIAS   |

**Note:**

Fixed output Mode:

M1 :  $V_{DD}=5\text{V}$  ,  $V_0=2.500\text{V}$  or  $V_{bias}$  ,  $V_{out} = V_0 \pm 2.000\text{V}@ \pm 20\text{mT}$  , sensitivity : 100 mV/mT ;

M2 :  $V_{DD}=3.3\text{V}$  ,  $V_0=1.650\text{V}$  or  $V_{bias}$  ,  $V_{out} = V_0 \pm 1.000\text{V}@ \pm 20\text{mT}$  , sensitivity : 50 mV/mT ;

## Characteristics Definitions

1. Sensitivity  $V_{\text{range}}$  [mV/mT].

Sensitivity is defined as the slope of the approximate straight line calculated by the least square method, using data of OUT voltage ( $V_{\text{out}}$ ) when the magnetic flux density ( $B$ ) is swept within the range of input magnetic flux density ( $B_{\text{in}}$ ).

2. Linearity Error  $\rho$  [%F.S.].

Linearity error is defined as the ratio of the maximum perpendicular deviation (MPD) to the full scale (F.S.), where MFD is the maximum difference between the OUT voltage ( $V_{\text{out}}$ ) and the approximate straight line calculated in the sensitivity definition. Definition formula is shown in below:

$$\rho = 100 * \frac{MFD}{F.S.} = 100 * \frac{MFD}{V_H - V_L}$$

Figure 3. Output characteristics of GS301

3. Ratiometric output error of sensitivity  $V_{\text{0erro}}$  [%] and ratiometric output error of Quiescent voltage  $S_{\text{erro}}$  [%].

The quiescent voltage ( $V_{\text{out0}}$ ) of the GS301 is constant, which means that it does not vary with the VDD. Error of Quiescent Voltage is defined as the difference between the  $V_H$  (or  $V_{\text{out0}}$ ) when the VDD is changed from 5.0v to  $VDD_1$  ( $4.75v < VDD_1 < 5.25v$  or  $4.5v < VDD_1 < 5.5v$ ). Definition formula is shown

in blow:

$$S_{\text{erro}} = \left[ \frac{V_{\text{out}}(VDD)}{V_{\text{out}}(5v)} - \frac{VDD}{5} \right] * 100$$

$$V_{0\text{erro}} = \left[ \frac{V_0(VDD)}{V_0(5v)} - \frac{VDD}{5} \right] * 100$$

4. Rise response time  $T_r$  [ $\mu\text{s}$ ].

Rise response time is defined as the time delay from the 90% of input magnetic field (B) to the 90% of the OUT voltage ( $V_{\text{out}}$ ) under the pulse input of magnetic flux density.

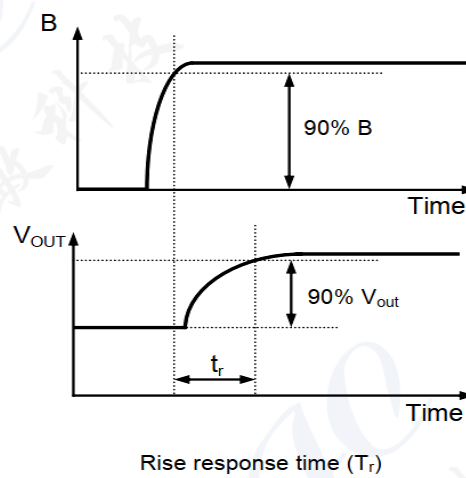

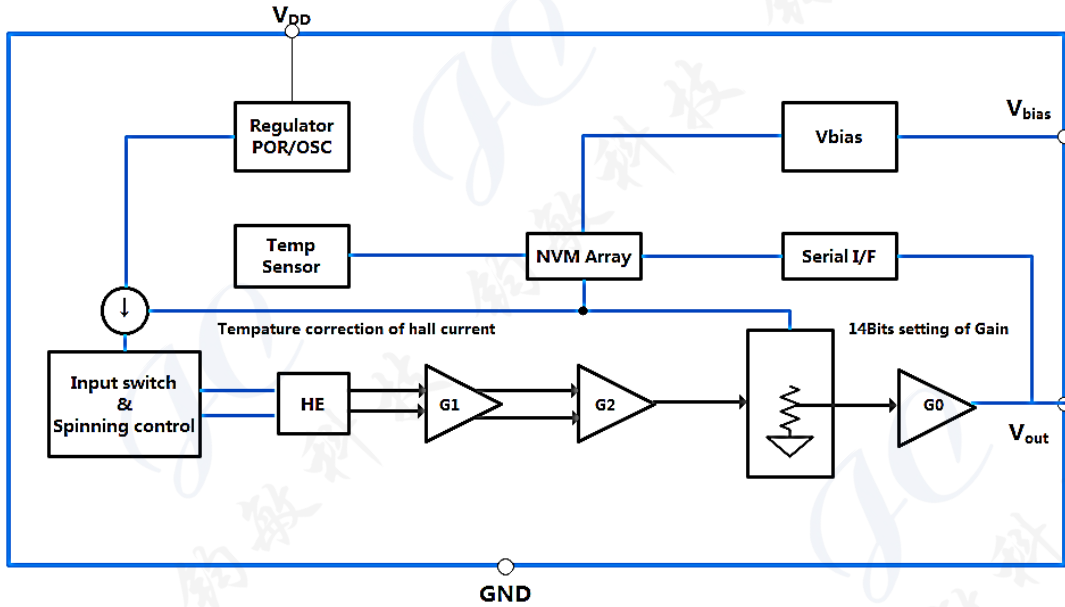

Figure 4. Definition of response time

5. Output Saturation Voltage  $V_{\text{out-SatH}}$  and  $V_{\text{out-SatL}}$ .

Output saturation voltage is defined as the saturated output at a fixed output current.  $V_{\text{out-SatH}}$  is defined as the chip's output voltage when the output current is -2 or 0.5mA in the positive magnetic field, and  $V_{\text{out-SatL}}$  is the chip's output voltage when the output current is -2 or 0.5mA in the negative magnetic field.
